

## Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

Read more about Early Journal Content at <http://about.jstor.org/participate-jstor/individuals/early-journal-content>.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact [support@jstor.org](mailto:support@jstor.org).

# THE ZOOCECIDIA OF NORTHEASTERN UNITED STATES AND EASTERN CANADA

CONTRIBUTIONS FROM THE HULL BOTANICAL LABORATORY 239

B. W. WELLS

This summary is based upon a completed descriptive account<sup>1</sup> of the zooecidia of the region studied, which is that phyto-geographic region dealt with by GRAY'S *New Manual of Botany* (7th ed., 1908). The only similar general statement preceding this is that of FELT (4), who has presented some approximate figures from an entomological standpoint pertaining to American insect galls. The mite (Eriophyidae) galls were not included in his discussion.

## Historical

Three local studies of zooecidia have been made which deserve mention in a brief historical account. COOK (2) in 1904 published the description of 66 galls from Indiana. JARVIS (7) in 1908 presented a catalogue of the insect galls of Ontario, comprising 221 species. STEBBINS (10) in 1910 described 205 species of galls collected in the vicinity of Springfield, Massachusetts. A post-humous catalogue of 233 southern New England galls by THOMPSON (11) appeared in 1915, edited by FELT. This also included a summary of American Cynipidae galls, listing 350 species.

For the sake of comparison a short summary of the European work will be given. HAIMHOFFEN (5) in 1858 presented 350 as the number of zooecidia for central Europe. SCHLECHTENDAL (9) in 1891 listed 1315 insect, mite, and nematode galls on the plants of Germany. KIEFFER (8) in 1901 published a synopsis of the zooecidia of Europe. There also appeared the same year a more exhaustive study in DARBOUX and HOUARD'S (3) systematic

<sup>1</sup> The work contains the description of 792 nematode, mite, and insect galls; half of this number will be supplemented by illustrations. Keys to the galls on the various plant genera have been made, the plant genus constituting the unit by which the galls have been grouped.

catalogue of the zooecidia of Europe and the basin of the Mediterranean, a work which in 1908 (supplement 1913) was expanded by HOUARD (6) into the largest systematic cecidological work in existence. This final general European work comprises the description of 1950 zooecidia.

### **Basis and plan of work**

The data from which the following summary is drawn were obtained during a period of 4 years, in which field studies in Connecticut, Ohio, and Kansas were supplemented by a thorough canvass of the highly scattered cecidological literature.

It may be of interest to mention the simple and, it is believed, practical scheme which has been followed in the arrangement of the 792 types described. The plant genus was made the unit under which the galls were grouped. This is in contrast to HOUARD's plan; he used the species, a plan which necessitated a vast amount of repetition, since innumerable galls occur on more than one species within the genus. It is a striking fact that very few galls are found upon more than one genus. In the study of the galls of the north-eastern United States, data concerning the plant species bearing the gall have been included with the descriptive material. To assist in locating the descriptions, keys were worked out for the genera having more than 6 or 8 species. A brief bibliography presenting the most important references was appended to each description.

The plant genera in the work have been arranged alphabetically. The galls under each genus have been aggregated according to the classification of the cecidozoons. It is thus evident that artificial classification has been pursued throughout. At the present time any classification of zooecidia must be artificial. The morphological data available, particularly of an anatomical nature, are far too meager to make possible anything approaching a natural classification.

### **Summary of numerical data**

In the case of all of the following figures presented, it should be understood that they are but approximations. So new is the field of systematic zooecidology in America, and so incomplete and

unsatisfactory are the data in innumerable specific instances, that at the present time any generalizations of a numerical nature cannot be accepted as expressing the exact condition.

A tabulated statement of the 792 galls known from the north-eastern quarter of the United States and eastern Canada, according to the cecidozoon orders and families, is as follows:

## DISTRIBUTION BY ANIMAL FAMILIES

Nematoidea (Nematohelminthes)		Gelechiidae.....	3
Anguillulidae.....	2	Elachistidae.....	2
Acarida (Acarina)		Sesiidae.....	1
Eriophyidae.....	87	Tortricidae.....	2
Hemiptera (Insecta)		Unclassified.....	10
Aphididae.....	70	Diptera	
Psyllidae.....	6	Trypetidae.....	7
Jassidae.....	1	Itonididae.....	383
Coleoptera		Hymenoptera	
Cerambycidae.....	2	Chalcidae.....	2
Buprestidae.....	1	Tenthredinidae.....	13
Lepidoptera		Cynipidae.....	194
Tineidae.....	1		

As FELT has pointed out, the family containing the most gall makers is the Itonididae, embracing in our region 47 per cent of the gall biota. The Cynipidae follow with 37 per cent. The other families are represented by much smaller percentages, the Coleoptera being barely represented with 3 ill-defined galls.

The distribution of the galls (except nematode) by the plant families on whose members they occur is as follows. The families are arranged in the sequence given in GRAY'S *Manual*.

## DISTRIBUTION BY PLANT FAMILIES

Pinaceae.....	13	Aristolochiaceae.....	2	Rosaceae.....	70
Typhaceae.....	1	Polygonaceae.....	2	Leguminosae.....	18
Gramineae.....	5	Chenopodiaceae.....	5	Euphorbiaceae.....	4
Cyperaceae.....	1	Nyctaginaceae.....	1	Anacardiaceae.....	10
Juncaceae.....	1	Portulacaceae.....	1	Aquifoliaceae.....	1
Liliaceae.....	9	Ranunculaceae.....	7	Celastraceae.....	1
Iridaceae.....	1	Magnoliaceae.....	2	Aceraceae.....	14
Salicaceae.....	60	Lauraceae.....	5	Balsaminaceae.....	3
Juglandaceae.....	64	Papaveraceae.....	1	Rhamnaceae.....	2
Betulaceae.....	18	Cruciferae.....	1	Vitaceae.....	20
Fagaceae.....	183	Saxifragaceae.....	5	Tiliaceae.....	7
Urticaceae.....	37	Hamamelidaceae.....	7	Malvaceae.....	1

DISTRIBUTION BY PLANT FAMILIES—*Continued*

Hypericaceae.....	2	Ericaceae.....	17	Labiatae.....	14
Violaceae.....	2	Primulaceae.....	1	Solanaceae.....	3
Cactaceae.....	1	Ebenaceae.....	2	Scrophulariaceae.....	2
Lythraceae.....	1	Oleaceae.....	6	Bignoniaceae.....	1
Onagraceae.....	1	Apocynaceae.....	1	Rubiaceae.....	3
Araliaceae.....	1	Asclepiadaceae.....	2	Caprifoliaceae.....	16
Umbelliferae.....	1	Convolvulaceae.....	1	Compositae.....	121
Cornaceae.....	11	Verbenaceae.....	3		

The striking fact brought out by this list is the extreme irregularity of the distribution. Many of the larger families have few or no galls, while on the other hand a few of the smaller families, particularly the Fagaceae, possess many cecidia. *Quercus* alone has 176 galls, of which 157 are cynipid types. FELT presents 277 as the approximate figure for the cynipid galls on the American oaks. The Cynipidae-*Quercus* situation in Europe as well as in America presents the most striking example of gall evolution within a single genus of plants related to a comparatively few (9 or 10) closely related genera of insects.

It is worthy of note that such large families as the Caryophyllaceae, Cruciferae, and Boraginaceae contain no gall-bearing species. The Umbelliferae possess but a single gall. The widely distributed tree species *Platanus occidentalis* does not bear any zoocecidia.

The problem in distribution on the plants presented by the preceding list is an exceedingly difficult one and probably cannot be answered on the basis of the physiological information at present available. This intimate and constant relation between specific insects and specific plants forms one of the most significant phenomena in the field of cecidology.

As far as data were obtainable, figures were worked out indicating the distribution of the galls on the plant parts, with the following result:

## DISTRIBUTION ON PLANT PARTS

On leaf blade (of these 52 are "blister" galls) .....	427	On roots.....	12
On petiole (most of these occur also on blade).....	47	On flowers.....	27
On stem (8 per cent of these occur also on the leaf).....	208	From buds forming a rosette type...	47
		From buds forming a solid concentric type.....	30

Slightly over half of the galls (53 per cent) occur on the leaf blade. This fact is of course related to the relatively large amount of embryonic leaf tissue exposed in the early stages of shoot development. In the cases of the stem, root, and bud galls numerous factors enter, but perhaps the most important is the factor of insect equipment necessary to place the larval cecidozoon in contact with the meristematic tissues.

Some figures pertaining to gall structure were obtained which are of interest. A few words of explanation are necessary before presenting the tabulation. Under the monothalamous galls were included those types which, so far as could be determined, are generally one-chambered, that is, the gall never is a structure constantly characterized by the confluence of the walls of two or more chambers as in the polythalamous condition. A few species are intermediate and were classified in the direction in which it was believed they leaned the more strongly. A number of galls, such as the erineum (hypertrophied epidermal cells) types, do not fall in either of the above categories and cannot be included in such a classification.

In those cases in which sufficient data were available, an attempt was made to study the galls on the basis of KÜSTER's division of cecidia into kataplasmas and prosoplasmas. By "kataplasmas" KÜSTER means those indefinite, indeterminate galls whose structure is developed through hyperplasia of embryonic tissue, the end product not becoming in its differentiation, orientation, and form of tissues fundamentally different from the normal plant part. "Prosoplasmas," on the other hand, are highly definite and determinate galls whose structure differs fundamentally from the normal plant, the tissues in their form and orientation characters constituting an aggregation of new qualities. These two groups intergrade, but the intergrading forms are relatively few in number and were classified according to what was believed to be the predominating condition. In all cases where data were not sufficient to pass judgment, the gall was omitted from the census.

Another set of figures presented is that based on KÜSTER's classification of galls into organoid and histoid types. An "organoid" gall is one in which an entire plant organ (leaf, stem,

internode, ovulary, etc.) as a unit suffers modification without a fundamental change in its morphology. The "histoid" galls are those more numerous types in which an entire plant organ is not involved, the gall being more or less definitely appendicular. This group includes all of the prosoplasmas and part of the kataplasmas.

#### DATA BASED ON NUMBER OF CHAMBERS

Monothalamous galls.....	408
Polythalamous galls.....	134
Non-chambered galls.....	67
Insufficient data to classify.....	183

The excessively large number of monothalamous forms is a fact related to the character of oviposition. If the eggs are habitually deposited in an aggregate manner, a polythalamous gall is almost certain to result, although there are striking exceptions to this. The great majority of larvae, however, begin their gall-making activity at sufficient distance apart to develop the common monothalamous types of cecidia.

#### KATAPLASMAS AND PROSOPLASMAS

Kataplasmas.....	395
Prosoplasmas.....	322
Insufficient data to classify.....	73

Viewed from an evolutionary standpoint, the kataplasmas represent the lower levels and the prosoplasmas the higher. That the latter have undergone a considerable expansion indicating relatively rapid progress in recent geologic time is evidenced by the relatively large number of prosoplasmas.

#### ORGANOID AND HISTOID GALLS

Organoid.....	215
Histoid.....	495
Insufficient data to classify.....	82

These figures have no special significance, perhaps, other than the indication of differences in the range of the gall stimulus. In the organoid types the stimulus is diffused over relatively large areas, inciting all of the tissues of one organ to hypertrophy and hyperplasia. In the histoid forms the stimulus only affects those tissues in a restricted area about the cecidozoon, these tissues responding in a definite and striking manner.

In addition to the above two tables KÜSTER has, in his classification of cecidia, furnished the basis for another table in his analysis of the prosoplasmas. These he divides into four groups: the leaf edge "roll" galls; the diverticulum or outpouching types; the "walled" (umwallungen) forms, whose walls grow up about the superficial larva; and the concentric (mark) cecidia whose larvae inaugurate gall formation from a point within the tissue. In the following list this classification was extended to include so far as possible the kataplasmas also, since a great many of these latter galls can properly be placed under some one of the preceding four groups. The 58 "rosette" and the 28 erineum types cannot be included.

## NUMBERS OF VARIOUS GALL TYPES

Leaf edge "roll" types.....	32	Concentric types	
Diverticulum types		On leaves.....	145
Leaf or leaflet fold along mid-vein .....	19	On stems.....	184
Pouch types proper.....	109	On other parts.....	36
Walled (umwallungen) types.....	87	Galls unclassifiable in the above categories .....	86
		Unclassified through insufficient data	94

The factors entering into the production of these various kinds of galls are many; a full discussion of them cannot be presented here. Attention, however, should be called to the two main groups, namely, those which are related to the plant and those related to the cecidozoon. The diverticulum galls are, with few exceptions, only known from the leaf, particularly the blade, since this organ only is sufficiently free from stereome tissues to make possible the characteristic pouching out on the side opposite the cecidozoon. The walled and concentric types can occur on any part of the plant, the latter constituting a much larger aggregation than any of the other kinds. Oviposition within the plant tissue or a migration inward on the part of the larva is necessary for the production of the concentric type of gall. Even in these cases constituting the highest galls, plant factors can exert a modifying influence. The study of the relative importance of the two groups of factors entering into cecidium morphogenesis in specific cases is one of the most valuable and suggestive in the field of zoocecidology.
